

Indiana DNR State Forest Properties
Report of Continuous Forest Inventory (CFI)
Summary of years 2011-2015

Joey Gallion
Forest Resource Information/Forest Inventory Program Coordinator

ACKNOWLEDGMENTS

The author thanks the many individuals who contributed to the inventory and analysis of this project. Primary field crew and QA staff over the 2011-2015 field inventory cycle included Craig Blocker, Darren Bridges, Adam Dumond, Joey Gallion, Gretchen Herbaugh, Abby Irwin, Nate Kachnavich, Greg Koontz, Derek Luchik, Sally Malone, Andrew Mason, Josh Nickelson, Andrew Reuter, Sean Sheldon, Mark Webb, and Madeline Westbrook. Pre-field work personnel included Gallion and Rebekah Price. Data management personnel included Gallion with much advice from Chuck Barnett, James Blehm, Bryan Blom, Kevin Nimerfro, Cassandra Olson, Larry Royer, Chip Scott, Jay Solomakos, and Jim Westfall. Report reviewers included Dan Ernst, John Friedrich, Scott Haulton, and John Seifert.

FOREWORD

This report provides an overview of forest resource attributes for State Forest land managed by the Indiana DNR Division of Forestry. The findings come from the continuous annual inventory conducted by the Forest Resource Information (FRI) Section of the Division of Forestry. The CFI inventory of Division of Forestry State Forest property is based on a sample of 3,937 plots located randomly across those lands (a total area of 156,185 acres), a sampling rate of approximately one plot for every 40 acres. Information in this report is gathered from quantitative and qualitative measurements that describe forest site attributes; stand characteristics; tree measurements on live and dead stems such as species, diameter, height, damage, tree quality; counts of regeneration; and estimates of growth, mortality, and removals. All estimates in this assessment are estimates of a population based on a statistical sample derived from the expansion of plot data and therefore may differ slightly from complete censuses of the population (e.g., total acres). Given the multitude of estimates of forest resource attributes, they are organized in “core tables” (e.g., forest land area vs. live tree volumes), which are updated annually.

This report is a summary of the five years of plot installation and data collection for the years 2011-2015, which constitute one entire cycle. With 20% of the plots measured annually, the 2015 plots were the same plots

measured in 2010, thus the 2010 data were replaced with the 2015. Because plot re-measurement (measuring the same plot at time two) has only occurred on 60% (2013, 2014 and 2015) of the plots thus far, change attributes such as growth, removals and mortality may not represent the entire sample with statistical significance yet.

EXECUTIVE SUMMARY/HIGHLIGHTS

This is the fourth reported results of the established continuous forest inventory (CFI), with the first three panels of annual plots (60% of the total sample) being re-measured. The goal of the first five years was to install all of the plots within the CFI sample frame and produce baseline resource estimates. These baseline data/estimates are now being used as a monitoring baseline to compare to future re-measurement data in compilation of statistical change estimates (e.g., tree growth/mortality). Details of the results are discussed below, and tabular results can be found in the additional “Part B” report. Baseline resource estimates of state forest properties are:

- 156,185 total acres; 150,932 forested acres with the balance in non-forest (i.e., campgrounds) and water
- 96% of the forested acres are hardwoods
- 85% of the forested acres are sawlog-sized stands
- Forests contain 58.6 million live trees
- Sugar Maple trees and seedlings are more abundant than any other species
- 337.1 million cubic feet of total live tree volume
- 1.159 billion board feet (Doyle) of sawlog volume
- White oaks followed by red oaks are the species groups with the most sawlog volume
- Over half of the sawlog volume is considered grade 1 or 2
- Japanese honeysuckle, multiflora rose, and stiltgrass are the most common invasive species

FOREST COMPOSITION

Area

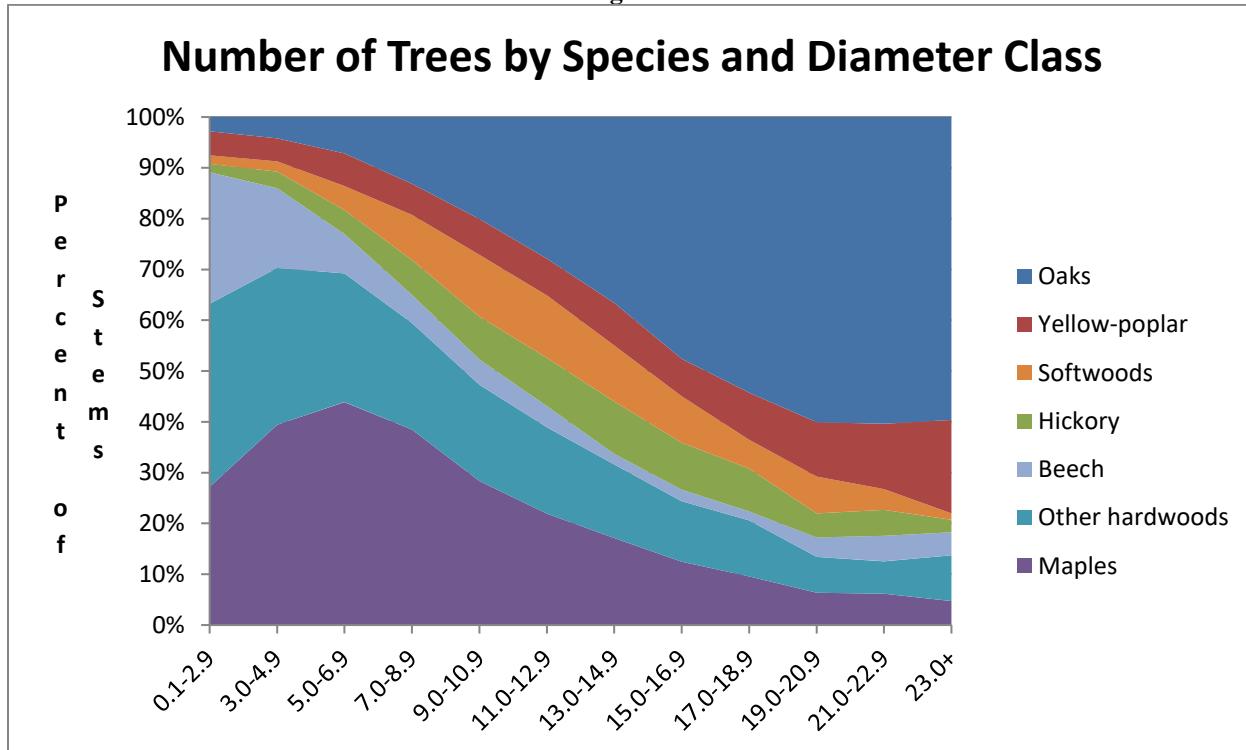

State Forest lands comprise approximately 156,185 acres located primarily in the southern third of Indiana. An estimated 150,932 of these acres are considered forestland (land considered stocked with trees or seedlings that is at minimum 1 acre in size and 120 feet in width), with the remaining ~5,300 acres being non-forest (open fields, campgrounds, rights-of-way, etc.), census water (bodies of water >5 acres and permanent rivers/streams), and non-census water (bodies of water <5 acres and small streams). Like most of Indiana’s forests, state forests are predominantly hardwoods with 96% of the total forest area classified as hardwood forest types. The primary hardwood forest types were white oak/red oak/hickory (35,493 acres, 23%), mixed upland hardwoods (20,980 acres, 14%), white oak (15,602 acres, 10%), and chestnut oak (13,240 acres, 9%) (Table 1). Eighty-five percent of the area was considered sawlog-sized stands (large diameter or 11.0” diameter breast height (d.b.h.)) and greater), with the remainder classified as poles (medium diameter or 5.0-10.9” d.b.h.) and seedling/saplings (small diameter or 1.0-4.9” d.b.h.) (Table 1).

Number of Live Trees

It is estimated that there are 58.6 million live trees on state forest lands. In terms of the total number of live trees, sugar maple and beech were the most abundant species at 12.1 million and 10.7 million trees, respectively (Table 2). More than half of those trees were less than 3 inches d.b.h., with 42.2 million being less than 5 inches d.b.h. An item of concern is the non-uniform distribution of the number of stems by diameter class for different

species (Figure 1). In this sample, all oak species combined represented about 3.1% of all saplings 1 inch to less than 5 inches d.b.h. The lack of oak seedlings/saplings and abundance of maple seedlings/saplings suggests a future decline of oak/hickory forest types as mature stands senesce.

Figure 1

Volume of All Live Trees

The net volume of all live trees, which includes growing stock, rough, and rotten trees, 5" d.b.h. and above was 337.2 million cubic feet. Hardwoods constituted 314.2 million cubic feet (cuft) or 93%. Oaks made up 145.1 million cuft or 43%. Maples were 47.5 million cuft or 14%. Yellow poplar was 45.6 million cuft or 13%. Hickories were 23.5 million cuft or 7% of the total volume (Table 3). Approximately 44.0 million cuft or 13% of the volume is in pole-sized trees (trees <11" d.b.h.) with the remainder being sawlog-size (11" and greater d.b.h.). 68.6 million cuft or 20% is 23" or greater d.b.h. (Table 3). It was estimated that 327.0 million cuft of the total volume was in growing stock trees, with the remainder in rough cull and rotten cull trees. These volumes are presented in cubic feet because board foot volume estimates are only calculated on sawtimber-sized trees (hardwoods 11" d.b.h. and greater, softwoods 9" d.b.h. and greater).

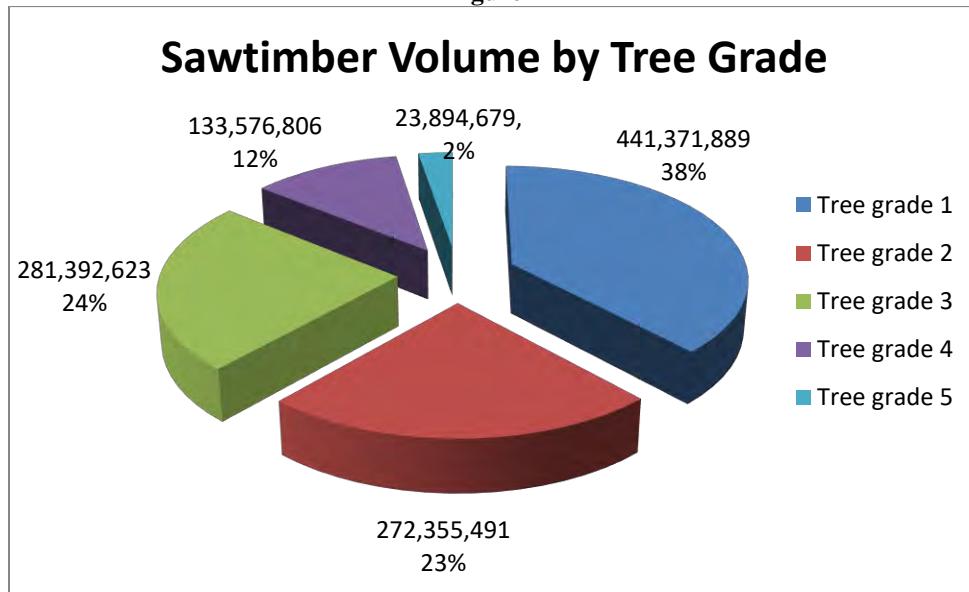

Volume of Sawtimber-sized Trees

The total net sawtimber volume was 1.159 billion board feet Doyle scale (7,682 bdft/acre). White oak was the most voluminous species with 219.3 million board feet (MMBF) or 19%, followed by yellow poplar, chestnut oak, and black oak with 167.1, 159.1, and 133.4 MMBF respectively (Table 4).

Grade of Sawtimber-sized Trees

Trees are graded using the Forest Service tree grading system. It grades the best 12' section in the butt 16' for hardwoods. Grade 1 must yield 10' clear of defects, grade 2 must yield 8' clear, grade 3 must yield 6' clear, grade 4 must only be sound (tie grade) and grade 5 has a non-gradable butt log (due to form or rot) but has a gradable upper log (above the butt 16' log). It was estimated that 441.3 MMBF of the total net sawtimber volume was grade 1 and 272.3 and 281.3 MMBF in grades 2 and 3 respectively (Figure 2). Ninety-nine percent of the sawtimber volume of trees had 0-10% cull deductions.

Figure 2

CHANGE ATTRIBUTES AND ANCILLARY DATA ITEMS

We continued to re-measure plots, beginning in 2013, now with 60% of the total sample (three annual panels) re-measured. The uncertainty associated with our estimates of change will sequentially decrease as each year's annual re-measurement is added to the sample until all CFI plots have been re-measured. With only a partial sample completed, the level of uncertainty with the estimations of change is somewhat higher than desired; however, we will report these attributes based on plot data and other outside data sources where applicable.

Growth

Net growth is defined as the gross or total growth less mortality. The average annual net volume growth of all live trees, which includes growing stock, rough, and rotten trees, 5" d.b.h. and above, was 3.44 million cubic feet per year. Hardwoods actually grew 3.69 million cuft/year or 107% of the total growth, while cedar and pines lost 250 million cuft/year. Oaks constituted 1.21 million cuft or 35%. Maples were 956,000 cuft or 28%. Yellow poplar was 635,000 cuft or 18%, and hickories were 521,000 cuft or 15% of the total growth (Table 5). Species groups showing negative growth (a negative growth value means that mortality was larger than the gross growth) besides the pines mentioned above, were sassafras, scarlet oak, ashes and elms. Approximately 700,000 cuft or 20% of the growth is in pole-sized trees (trees <11" d.b.h.) with the remainder being sawlog-sized (11" and greater d.b.h.).

Looking at sawlog-sized volume growth, trees collectively grew an average of 10.97 million board feet (Doyle) annually. Hardwoods actually grew 11.36 million bdft/year, while cedar and pines lost 387,000 bdft/year. Oaks constituted 3.5 million bdft or nearly 32%. Yellow poplar was 2.54 million bdft or 23%. Maples were 1.79 million bdft or 16%. Hickories were 1.62 million bdft or nearly 15% of the total growth (Table 6). Species or species groups showing negative growth (a negative growth value means that mortality was larger than the gross growth), besides the pines mentioned above, were elms and scarlet oak.

Mortality

The average annual volume mortality of all trees was 4.53 million cubic feet per year. Hardwoods accounted for 3.81 million cuft/year or 84% of the total mortality. Yellow poplar was 613,000 cuft or 13%, and four oak species were the next individual species with the most volume lost to mortality. Black oak lost 418,000 cuft. Northern red oak lost 391,000 cuft. White oak lost 356,000 cuft. Chestnut oak lost 345,000 cuft. Collectively, all the oak species accounted for 1.69 million cuft or 37% of all mortality (Table 7).

Looking at sawlog-sized volume mortality, forests lost an average of 10.8 million board feet (Doyle) annually. Hardwoods accounted for 8.88 million bdft/year or 82%. Oaks constituted 5.3 million bdft or nearly 49%. Yellow poplar was 1.5 million bdft or 14%. Ashes were 637,000 bdft or 6%. Maples were 614,000 bdft or 5% of the total mortality (Table 8).

Some of the high mortality is easy to understand. Ash decline can be contributed to the emerald ash borer (EAB). Ash will continue to increase in mortality loss, the elms to Dutch elm disease, and sassafras probably due to a combination of the canker diseases that favor that species. Others, however, are a bit more complex. Several possible factors such as intermittent recent droughts over the last 20 years, an outbreak of tulip scale attacking yellow poplar a few years ago, other possible insects and diseases, and natural age progression of many individual tree species could be contributing to the volume lost to mortality.

Just looking at volume, one may think all oaks are on a tremendous downward trend. But looking at the volume as a percentage of live volume by species, things aren't totally doom and gloom, as Figures 3 and 4 show. With the white oak family species, one can see "normal" mortality trends until you get to the upper diameter classes where a slight uptick is present, especially with white oak. Compared to the red oak family's trends, that uptick is more pronounced in all species except pin oak.

This high mortality in oaks and other species is concerning. We will continue to monitor mortality levels in the future while investigating deeper into the root causes of excess mortality in forests.

Figure 3

Mortality of White Oak Species Group

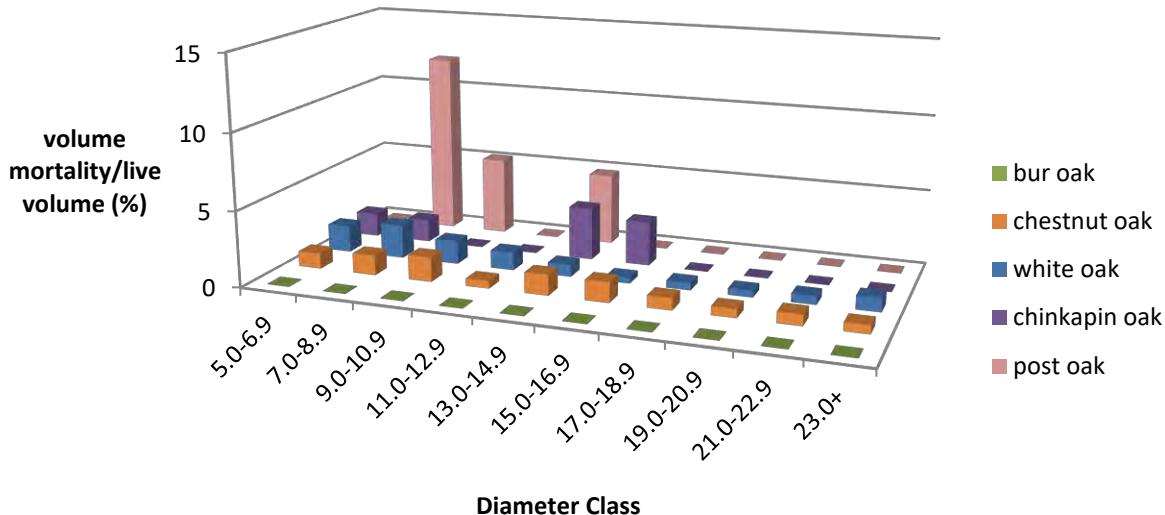

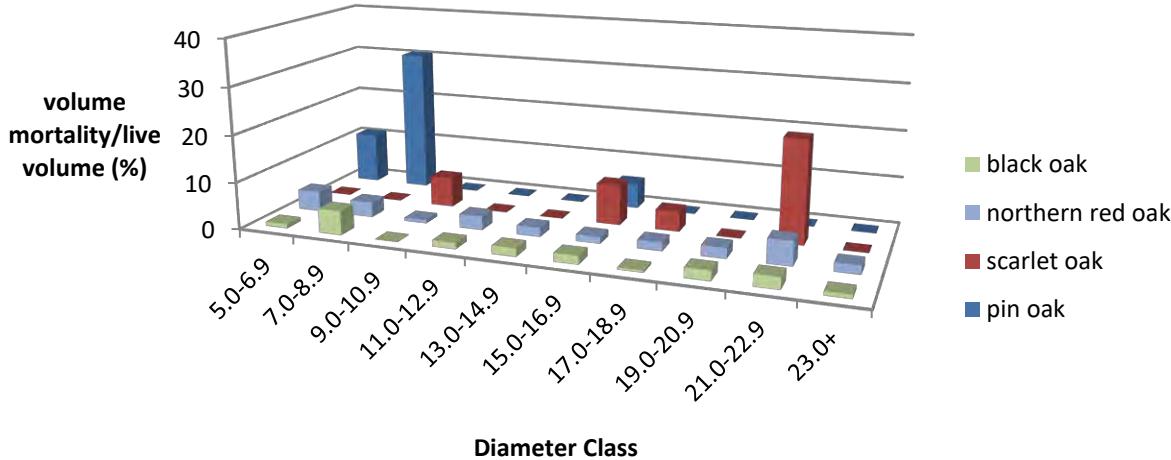

Figure 4

Mortality of Red Oak Species Group

Removals

The average annual volume removals of all trees was 3.77 million cubic feet per year. Hardwoods accounted for 3.67 million cuft/year or 97% of the total removals. Yellow poplar was 851,000 cuft or 22%, followed by black oak at 610,000 cuft, white oak at 342,000 cuft, and sugar maple at 290,000 cuft (Table 9).

Looking at sawlog-sized volume removals, 12.0 million board feet (Doyle) was removed annually. Hardwoods accounted for 11.8 million bdft/year. 4.4 million bdft or 36% of the removals were oaks, while yellow poplar and maples followed at 3.6 million bdft or 30% and 1.0 million bdft or 8%, respectively (Table 10).

Standing Dead Trees

There were an estimated 1.7 million standing dead trees 5" d.b.h. and greater. The individual species with the largest number of standing dead trees was sassafras with 283,000 stems. Virginia pine was second with 173,000 standing dead trees with white oak, chestnut oak and yellow poplar following with 162,000, 141,000 and 132,000 standing dead trees, respectively (Table 11). As with the number of live trees, the number of standing dead trees decreased as the diameter increased. Of the 1.7 million standing dead trees, 935,000 had a diameter from 5-9" d.b.h., 589,000 were from 9-15" d.b.h., 152,000 were from 15-19" d.b.h., and the remaining 109,000 were 19" d.b.h. and greater (Table 11).

Invasive Species

If present, crews identify any invasive species found on plot and measure the area of the plot that species occupy. These area estimates are then expanded to the entire 150,932 forested acres to estimate a total area that each invasive species occupies. Some plots may have multiple species present, while the majority of plots are free from invasive species. There were an estimated 1,890 cumulative acres (about 1.25%) with invasive species present. Japanese (vine) honeysuckle and multiflora rose are the most prevalent, covering approximately 642 and 595 acres, respectively. Stiltgrass (Nepalese browntop) is next, covering 199 acres. Other species of interest were black locust and bush honeysuckle (approximately 100 acres each), autumn olive (81 acres), and garlic mustard (54 acres). Of note it appears that bush honeysuckle and multiflora rose are more prevalent in forests with higher tree basal area content.

SUMMARY

The establishment of a statistically rigorous forest resource monitoring program modeled after many aspects of the nation's forest inventory program (FIA) on Indiana's state forests is already yielding a baseline of resource information. Estimates from this baseline compare favorably to prior estimates available from the FIA program and previous inventories conducted on state forest properties. As estimates of state forest land resource attributes were either sampled at a lower plot intensity (FIA) or using inconsistent methodologies (stand-exams), estimates from Indiana's state forest land CFI program may be considered as a superior baseline.

Change estimates (growth, mortality and removals) will become statistically stronger in the future as more plots are re-measured to provide reliable estimates. The CFI system was not designed to produce change estimates until plots are re-measured (beginning in 2013, with 20% measured annually).

INVENTORY METHODS AND TECHNIQUES

In order to better understand Indiana's public forests, to assist in providing public disclosure for forest management, and to better address third party certification from SFI and FSC, the Division of Forestry began designing a Continuous Forest Inventory (CFI) system in 2007. The USDA Forest Service Forest Inventory and Analysis (FIA) program was chosen as the program to mirror for several reasons. The Indiana DNR began to negotiate with FIA to build the CFI system to meet the certification audit requirements and yet coincide with the

existing FIA standards. A unique system was designed, and implementation of plot establishment on the forest began in 2008. The plots were spaced such that an approximately equal number of plots per year per state forest property (an annual panel) would be completed. Annually, these panels can stand alone as an independent survey, and therefore some results of significant value can be analyzed and reported on an annual basis. In 2013 we began to re-measure the plots that were established and measured in 2008. Therefore, now three annual panels of plots (60% of the total sample) have been updated with 2013, 2014 and 2015 data and the 2008, 2009 and 2010 data were dropped from the total estimate calculations. Later years will follow the same protocol.

Quality Assurance/Quality Control

The CFI program is the key program that provides the information needed to assess the status and trends of the Division of Forestry's managed forest lands. The goal of the CFI is to assure the production of complete, accurate and unbiased forest information of known quality. Specific measurement quality objectives (MQO) for precision are designed to provide a window of performance that we strive to achieve for every field measurement (quality assurance or QA). Quality control (QC) procedures include direct feedback to field staff to provide continual real-time assessment and improvements or refinements of field staff performance. These data quality goals were adapted from the USFS FIA program goals, which were developed from knowledge of measurement processes in forestry and forest ecology.

At the heart of CFI quality is extensive staff training and expertise. Field staff members meet minimum forest inventory requirements of a forestry education and background. In addition, each field staff member begins with an extensive on-the-job training program. Once field staff members have a comfort level for what is expected of them, they begin production data collection on their own.

To quantify and evaluate how the field staff is performing, a second measurement (quality check) taken on a sample of completed field plots is performed by a trained and certified QA staff. This technique is done blindly, or without the production crew data on hand, and then the two sets of data are compared, analyzed and scored to the given MQO standards. Three percent of the plots are pre-selected and considered mandatory quality-check plots. The field staff does not know which plots are mandatory checks. Field staff turn in completed data at given time intervals, and if no mandatory check plots are in that batch of production plots, then a random plot (non-mandatory) is picked to perform a quality check so that timely feedback can continuously be provided to the production field staff.

Each datum measured in the field has an associated MQO for precision. This is an assigned tolerance or acceptable level of measurement error, and measure the ability of field staff to make repeatable measurements or observations within the assigned tolerances. In the analysis of QA data, an observation is within tolerance when the difference between the production field staff data and the quality-check data do not exceed the assigned tolerance or MQO for that data element. For some data elements, the tolerance is "no error," thus only observations that are identical are within tolerance. For example, the tolerance for measurement of tree DBH is +/- 0.1 inch for each 20.0 inches of diameter of a live tree, with the MQO for DBH set at 95%. The quality of the data is evaluated by comparing the desired rate of differences within tolerance (as a percent of observations) to the MQO. In the example above, the objective for DBH would be that 95% or more of the DBH observations are within +/- 0.1 inch for each 20.0 inches of diameter for all trees measured by both production field staff and QA staff.

Analysis of this QA dataset assures two things for the program: 1) a measurement of the accuracy of the data being collected and 2) an indicator of future training needs and refinement of the production field staff. With continuous program monitoring and productive feedback to field staff, the QAQC portion of the CFI program should continually improve the quality of the data over time.

Field Production Protocols

With the annual inventory system, about one-fifth of all field plots are measured each year. After five years, an entire inventory cycle is completed. After the first five years, results can be analyzed and reports created as a moving five-year average. For example, Indiana CFI will be able to generate a report based on inventory results for 2008 through 2012 (the first report), 2009 through 2013 (second report), 2010 through 2014 (last year's report), or 2011 through 2015 (this year's report), and so on.

Field plots of the inventory consist of installing and measuring of the annual sample of field plots (panel) on each state forest. It was determined for desired CFI precision standards that the sampling intensity would be one plot for approximately every 40 acres. For efficiency, it was also determined that an entire compartment of a state forest property would be established and measured within the same panel. INCFI used the FIA non-overlapping hexagonal method to assist with establishing plot locations using Arc Map.

Field crews measure vegetation on plots based on FIA standards and protocols with few exceptions. Instead of the four-subplot design that FIA uses, Indiana CFI only uses one 24-foot-radius ($1/24^{\text{th}}$ acre) circular subplot with the offset 6.8-foot-radius ($1/300^{\text{th}}$ acre) microplot. Trees with a d.b.h. 5 inches and larger are measured on the 24-foot-radius circular subplot. All trees 1 inch d.b.h. and larger are measured on the 6.8-foot-radius circular microplot located 12 feet east of the center of the subplot. Both tree and forest measurements are collected. Some measurements include:

- General stand characteristics such as forest type, stand size and age, slope and aspect, and any recent disturbances
- Tree species, diameter, several different heights, damage, amount of rotten or missing wood, crown measurements, and tree quality
- Counts of tree regeneration
- Presence of identified invasive plants

Specific field protocols can be found in the Indiana CFI Field Data Collection Procedures for Plots Field Manual (internal document). With few exceptions, the FIA field manual (version 4.0) will suffice and is readily available online at http://www.fia.fs.fed.us/library/field-guides-methods-proc/docs/core_ver_4-0_10_2007_p2.pdf.

Estimation Errors or Quality of the Estimates

The four primary sources of error common to all sample-based estimates are sampling, measurement, prediction, and non-response error. For each of these sources of error, a definition within the context of the CFI inventory is provided along with a discussion of methods used to quantify and reduce this error.

Sampling Error

The process of sampling (selecting a random subset of a population and calculating estimates from this subset) causes estimates to contain error they would otherwise not have if every member of the population had been observed and included in the estimate. The CFI inventory of Division of Forestry State Forest property is based on a sample of 3,867 plots located randomly across those lands managed by the Division of Forestry (a total area of 156,265 acres), a sampling rate of approximately one plot for every 40 acres. Along with every estimate is an associated sampling error that is typically expressed as a percentage of the estimated value but that can also be expressed in the same units as the estimate or as a confidence interval (the estimated value plus or minus the sampling error). This sampling error is the primary measure of the reliability of an estimate. A sampling error can be interpreted to mean that the chances are two out of three that had a 100-percent inventory been taken using these methods, the results would have been within the limits indicated (i.e., 67-percent confidence interval).

The sampling errors for State-level estimates of the major attributes presented in this report are shown in the Part B tabular data report. The estimators used by CFI are unbiased under the assumptions that the sample plots are a random sample of the total population and the observed value for any plot is the true value for that plot. Deviations from these basic assumptions are not reflected in the computation of sampling errors. The following sections on measurement, prediction and nonresponsive error address possible departures from these basic assumptions.

Measurement Error

Errors associated with the methods and instruments used to observe and record the sample attributes are called measurement errors. On CFI plots, attributes such as the diameter and height of a tree are measured with different instruments, and other attributes such as species and crown class are observed without the aid of an instrument. On a typical CFI plot, six to 12 trees are observed, with 15 to 20 attributes recorded on each tree. In addition, many attributes that describe the plot and conditions on the plot are observed. Errors in any of these observations affect the quality of the estimates. If a measurement is biased (such as tree diameter consistently taken at an incorrect place on the tree), then the estimates that use this observation (such as volume) will reflect this bias. Even if measurements are unbiased, high levels of random error in the measurements will add to the total random error of the estimation process.

To ensure that all CFI observations are made to the highest standards possible, a regular program of quality assurance and quality control is an integral part of all CFI data-collection efforts, as described previously.

Prediction Error

Errors associated with using mathematical models (such as volume models) to provide observations of the attributes of interest based on sample attributes are referred to as prediction errors. Area, number of trees, volume, biomass, growth, removals and mortality are the primary attributes of interest presented in this report. Area and number of trees estimates are based on direct observation and do not involve the use of prediction models; however, CFI estimates of volume, biomass, growth, removals and mortality use model-based predictions in the estimation process. Models are used to predict volume and biomass estimates of individual tree volumes. In the future, change estimates such as growth, mortality and removals will be based on these model-based predictions of volume from both the future plot re-measurements and the measurements taken in this first inventory.

Users of CFI estimates should be aware of the possible prediction errors in CFI estimates. In comparing CFI estimates to other data sources, users need to be aware of the prediction models used in both estimates. If both estimates are based on the same prediction models with matching fitted parameter values, then the prediction bias of one estimate should cancel out that of the other estimate. If the estimates are based on different prediction models, then the user should be aware of the prediction error of both models.

Non-response Error

Non-response error refers to the error caused by not being able to observe some of the elements in the sample. In CFI, non-response occurs when crews are unable to measure a plot (or a portion of a plot) at a selected location. Non-response falls into the following three classes:

Denied access – Entire plots or portions of plots where the field crew is unable to obtain permission from the landowner and is therefore unable to measure the trees on the plot. This is not applicable in the CFI system on State Forest properties, but could apply to the CFI system on the classified forest program.

Hazardous/inaccessible – Entire plots or portions of plots where the conditions present prevent a crew from safely getting to the plot or measuring the trees on the plot.

Other – Plots where the field crew is unable to obtain a valid measurement for a variety of reasons other than those stated above.

Non-response has two effects on the sample. First, it reduces the sample size. The reduced sample size is reflected in the sampling errors discussed in that section. Second, non-response can bias the estimates if the portion of the population not being sampled differs from the portion being sampled. Fortunately, in CFI, unlike many survey samples, non-response rates are relatively low. The non-response plots in this inventory were not permanently removed from the CFI system of plots. In future inventories we will again attempt to measure these plots. At that time we may be able to obtain permission to access these plots (for the classified forest system), the hazardous conditions may have changed, or other circumstances that caused us to not measure plots could be different.

Data Management

These collected data are then imported, housed, and processed using a sophisticated Oracle database system. This Oracle system consists of three different but linked databases: MIDAS, NIMS and FIADB. Midas is the pre-field database and historical data housing unit. NIMS is the post-field housing and processing database. FIADB is the database housing the presentation tables. So this Oracle system not only houses the data but also processes and readies the data for distribution. “Processing” the data combines certain measurements to determine some calculated estimates (e.g., using tree diameter, tree height, site index measurements, tree species, etc. to estimate tree volume using a volume equation).

Distribution is accomplished by eventually loading the post-processed data (FIADB tables) into a customized Access database that is similar in functionality to the USFS FIA EVALIDator online tool. This Access database is used to assist with the analysis and interpretation of data. One can create customized tables with error estimates using this EVALIDator Access database.

Oracle processing protocols are documented as well (several internal documents). Most protocols are scripts written in sequel programming code or are instructions for the processing of the data and are intended for the database manager or advanced user only. An Access EVALIDator User Guide was created (beta version – work in progress) with the intent of being used as a reference guide after a training session of how to use EVALIDator has been attended.
